

Private Git Server on Google Drive

This setup creates a "Private GitHub" environment on your Google Drive. It allows for reliable backups and multi-device access without the constant file-syncing interference that disrupts Docker and high-frequency coding.

Why "Bare" Repos? A `--bare` repository contains only the Git data (the `.git` folder contents) without a "working tree" of files. This makes it a perfect, stable target for pushing/pulling via Google Drive.

1. Initializing a New "Server" Repo

Repeat these steps on your Mac for every project you want to back up to Drive.

```
# 1. Navigate to your Google Drive folder
cd "/Volumes/GoogleDrive/My Drive"

# 2. Create a folder to hold your backups
mkdir -p GitBackups/ProjectName.git
cd GitBackups/ProjectName.git

# 3. Initialize the backup target
git init --bare
```

2. Connecting Your Local Project

Go to your actual coding folder (where your 30k lines of code and Dockerfile live).

```
cd ~/path/to/your/local/code

# Link your local repo to the Drive backup
git remote add cloud "/Volumes/GoogleDrive/My Drive/GitBackups/ProjectName.git"
```

3. The "Sync" Commands (Push & Pull)

Backing Up (Push)

When you want to save your work to the cloud:

```
git push cloud main
```

Updating Local Code (Pull)

If you worked on another machine and want to bring those changes to this Mac:

```
git pull cloud main
```

4. Cloning to a New Machine

To set up your project on a second computer for the first time:

```
# Go to your developer folder
cd ~/Documents/Developer

# Clone directly from the Google Drive path
git clone "/Volumes/GoogleDrive/My Drive/GitBackups/ProjectName.git"
```

5. Automation Shortcut

Make it a one-word command. Add this to your `~/.zshrc` file:

```
alias packup="git push cloud main"
```

After saving, run `source ~/.zshrc`. Now you can just type `packup` to back everything up instantly.
